

How to Interpret Z_{DR} Shade Charts

Lindsey M. Richardson, W. David Zittel,
Robert R. Lee, Jessica A. Schultz, Dan B.
Frashier, Amy E. Daniel

What's a Shade Chart?

- A graphical way to monitor Z_{DR} bias from a **single** radar site
 - Information from most recent month and 6 months prior

What's a Shade Chart? (Cont.)

- Based on 3 independent external target methods:
 - Light Rain
 - Dry Snow
 - Bragg Scatter
- Event characteristics are different between the methods

Why do we care about Z_{DR} Bias*?

- Z_{DR} bias shows the amount of error in ZDR Offset
- Z_{DR} bias can have adverse affects on Quantitative Precipitation Estimation (QPE)
 - A positive Z_{DR} bias results in underestimation
 - A negative Z_{DR} bias results in overestimation
- Z_{DR} affects other products as well
 - Melting Layer Detection Algorithm (MLDA)
 - Particularly “wet snow”
 - Hydrometeor Classification Algorithm (HCA)
 - Specific Z_{DR} thresholds for categories

* This is not the same as ZDRB (ZDR Offset)

Why external targets?

- External targets act as an estimation metric independent from the built-in hardware estimates
 - Additional measurement to verify built-in hardware results
- Methods work with operational scanning strategies and products

What's on a Shade Chart?

Let's focus on one of the methods for more details

Did you notice?

- The dashed lines?
- The black numbers at the top of the shading in places?
- The gap in shading?
- Each subplot contains information from an independent method?
- The chart has a trend in time?

Let's focus on a single subplot and explore these details

Layout of Each Subplot

Z_{DR} Bias Estimates from Events

Site A Systematic Z_{DR} Bias Jun'15-Nov'15

Based on Δ_{Rain} (dB)

Main Title at top (on top subplot only)

- Many, highly-varying scatter points
 - Events may vary greatly from one to another
 - Events are defined per method in later slides
- Events are OK, but what if we took a 7-day median?

Grouping for Shading

Site A Systematic Z_{DR} Bias Jun'15-Nov'15
Based on Δ_{Rain} (dB)

Zoom in to focus on smaller time scale

7-Day Running Median

- For each 7-day grouping, a median is calculated from the points
 - Days 1-7, 2-8, 3-9, etc.
- Shading vertex placed on middle day of 7-day set
- Each of the colored boxes above represent a separate set

7-Day Median Calculation

Site A Systematic Z_{DR} Bias Jun'15-Nov'15
Based on Δ_{Rain} (dB)

Go from just having points...

7-Day Median Calculation

Site A Systematic Z_{DR} Bias (7-day median shading) Jun'15-Nov'15
Based on Δ_{Rain} (dB)

...to having shading.

7-Day Median Shading

Site A Systematic Z_{DR} Bias (7-day median shading) Jun'15-Nov'15
Based on Δ_{Rain} (dB)

- Long-term median trend shows a continuing bias
 - Positive (red-shaded) values are considered warm or high
 - Negative (blue-shaded) values are considered cool or low
- Sites are beyond recommended limits if the shading is regularly above (below) the dashed 0.2 dB (-0.2 dB) line

7-Day Median Shading Cont.

- Medians beyond the y-axis limits are shown as a number near the top
- No shading means the data is either missing, not available, or equals 0.0 dB exactly
- Will interpolate if only missing one shade value between two valid points

7-Day Median Shading Cont.

Where are the scatter points?

- Event scatter points outside of the y-axis limits (± 0.5 dB) are not shown
- Recall that **median** values from shading outside of the limits are represented by the black numbers at the top

Compare Trends from Multiple External Target Methods

Site A Systematic Z_{DR} Bias (7-day median shading) Jun'15-Nov'15

Based on Δ_{Rain} (dB)

Nov'15 WMean
(All 3 Methods):
+0.17

Light Rain

Dry Snow

Bragg

What do the methods detect?

Each method is independent and includes distinct caveats

- 2 Methods Related to Precipitation:
 - Light Rain (liquid precipitation)
 - Dry Snow (frozen precipitation)
- 1 Method Related to Clear Air
 - Bragg scattering associated with refractivity gradients

Click [here](#) to skip method details and jump to interpretation

Light Rain Method

- Medians are calculated for six separate reflectivity (Z) categories
 - Categories are inclusive and set as (in dBZ):

19.0-20.5	21.0-22.5	23.0-24.5	25.0-26.5	27.0-28.5	29.0-30.5
-----------	-----------	-----------	-----------	-----------	-----------

- An expected Z_{DR} value (in dB) based on climatology is subtracted from the median of each category:

0.23	0.27	0.32	0.38	0.46	0.55
------	------	------	------	------	------

- Subtraction factor can **bias Z_{DR} low**

Light Rain Method Cont.

- Daily Median (scatterpoints on chart)
 - Median of the 12-volume average values reported in the ASP* message (ZDR Stats)
 - The 12-volume average uses the most recent 12 volume scans
 - Results from the six separate categories are averaged each volume scan into a single number
- Filters include:
 - Range > 20km
 - Elevation > 1°
 - Heights up to 1 km below the melting layer
 - SNR ≥ 20
 - $0.98 < \rho_{HV} < 1.05$

* The ASP is a product version of the RPG Status Log

Dry Snow Method

- Only uses bins classified as Dry Snow (dry aggregates) by the Hydrometeor Classification Algorithm (HCA)
 - Snow does NOT have to be reaching the surface
- Extra filters:
 - Range > 20 km
 - $15 \text{ dBZ} < Z < 25 \text{ dBZ}$
 - Elevations > 1°
 - $\text{SNR} \geq 20 \text{ dB}$,
 - $0.98 < \text{RHO}_{\text{HV}} < 1.0$
 - $\text{PHI} < 100^\circ$
 - Bins must be completely above the melting layer
 - Must have at least 500 Z_{DR} bins that pass filters per volume
 - Standard deviation $Z_{\text{DR}} < 0.5 \text{ dB}$

Dry Snow Method Cont.

- Daily Median Events
 - Median of the 12-volume averages, reported in the ASP, of the Z_{DR} values that pass the filters
 - Subtract **0.2 dB** (climatological value of dry snow) to get the Event bias
- Can be estimated at the same time as a rain Event as long as dry aggregate snow is observed above the melting level
- Dendrites and Platelets can **bias Z_{DR} high**
- Subtraction factor can **bias Z_{DR} low**

Note: Aggregates are clumps of frozen precipitation (particularly ice crystals)

Bragg Scatter Method

- Bragg distinguished by refractivity gradients generally caused by turbulent eddies
 - **Intrinsic $Z_{DR} = 0.0$ dB** (no subtraction factor needed)
 - Often found at the top of the Convective Boundary Layer and Marine Boundary Layer
- Filters:
 - VCP 32 and 21 only (will be available in all VCPs in B18)
 - 10-80 km in range only
 - $Z < 10$ dBZ
 - $|V| > 2$ m/s
 - $W > 0$ m/s
 - $SNR < 15$ dB
 - $0.98 < \rho_{HV} < 1.05$
 - Elevations 2.5-4.5°

Bragg Scatter Method Cont.

- Additional filters:
 - Z at the 90th percentile ≤ -3 dBZ (precipitation filter)
 - Need at least 10,000 bins that pass filters
 - Inter-Quartile Range (IQR) < 0.9 (biota filter)
- Daily Median Events
 - The mode of the histogram is calculated each volume
 - 12-volume average of the modal values is reported in the ASP under ZDR Stats (Bragg)
 - Medians of 12-volume averages count as the daily event

Bragg Scatter Method Cont.

- Precipitation contamination can **bias Z_{DR} high**
- Return from Bragg scattering has a weak signal, and if noise is comparable to the signal it could **bias the estimate towards 0.0 dB**
 - Assuming the noise estimates are similar in both H and V channels

Method Availability

- Light rain is less available during the cool season especially at northern continental sites
- Dry snow can be found year round at most sites
- Bragg scatter less available due to stringent filters
 - Also less available in the warm season due to biota contamination

Rely on More Than One Method When Possible!

- When all 3 methods show a similar bias, there is high confidence in the indicated bias
 - All methods are not always available
- The **trend** is the important aspect
 - Need **at least a month** of data to establish a baseline

Full-Chart Recap: Compare the Methods

- Z_{DR} is high (above and near the positive limit) for the majority of the time in all three methods
- Focus on most recent month
- Compare with previous months for overall trend

Monthly Summary

- The median of each method is calculated for the most recent month (not shown)
- These medians are then used to calculate a Weighted Mean (WMean) Estimate (displayed in the top-right box)
 - Weights are based on method estimation accuracy
 - Bragg scatter is given the most weight, snow the next most, and rain the least

Monthly Summary

- The monthly WMean box is color coded (matches shade color when beyond-recommended-limits)
- It will say NaN (Not-a-Number) if there are no estimates for an entire month

Shade Interpretation: “Good” Site

Within Limits

Close to zero
and within
recommended
limits for all
methods

Shade Interpretation: Another “Good” Site

Within Limits

Alternating
red/blue
around zero
(within
limits) is OK

Shade Interpretation: Warm Bias

Beyond Limits

A warm bias
causes QPE
underestimation

Shade Interpretation: Cold Bias

Beyond Limits

A cold bias
causes QPE
overestimation

Shade Interpretation: Site Improves

Site had a large negative bias and improved closer to within limits

Shade Interpretation: Disagreement

Disagreement possible due to the independent method caveats

- Site bias is likely around 0.0 dB in this case
- Within limits on both sides, so less priority to take action

6-Month Time Window

- Shading features are consistent for a given month

Site H
End Month:
September

Note how
the circled
areas move
with time in
the next two
slides

6-Month Time Window

- Features move to the left

Site H
End Month:
October

6-Month Time Window

- Some features move off with the moving time window

Site H
End Month:
November

Previous months are archived and available

Redundant Sites (Ch1 Example)

Site I Ch1 Systematic Z_{DR} Bias (7-day median shading) Jun'15-Nov'15
Based on Δ_{Rain} (dB)

Nov'15 WMean
(All 3 Methods):
NaN

Attempt to isolate
estimates per channel
- The ROC will send
charts for each channel

Redundant Sites (Ch2 example)

Sometimes the plots only have info in one Channel. This may be a plotting error if the site is routinely switching channels as suggested.

Summary

- A shade chart is a quick way to assess if a site has a Z_{DR} bias and the approximate magnitude of the bias
 - Sites with biases outside of the ± 0.2 dB range are considered to be **Beyond-Recommended-Limits**
 - Z_{DR} bias adversely affects several products, especially QPE
- Charts can help track when maintenance was performed and if it helped (e.g., had a large bias and was corrected to within limits)
 - Can also see if a site has a new or drifting hardware issue (e.g., site was within limits and jumped to a large bias)

Summary Cont.

- We are still exploring the details of the external target methods!
 - External targets are an independent, extra metric to the built-in hardware estimates that work with operational scanning strategies and products
 - Each method has unique caveats and variability in accuracy
 - Some aspects of variability remain unknown
- By using multiple methods, there is higher confidence a site does or does not have a bias

Within Limits is OK!

- Achieving an exact Z_{DR} bias estimates of 0.0 dB can be difficult because the variability of the methods and built-in hardware often exceed ± 0.1 dB
 - The trend of median bias estimates falling within ± 0.2 dB should be sufficient for most algorithms and visual analysis
